

The background of the slide features two globes, one in the upper left and a larger one on the right. Both globes are covered in a dense pattern of small white dots, representing city lights or data points, against a solid black background.

INTRODUCTION AND CONTEXT

- Tesla announced full self driving in 2016
- We still don't have the future they promised

WHY IS THIS?

- There is a severe lack of training data
- There are many drivers but they are not connected to these companies on any one platform that standardizes the data.
- We fixed this

OUR SOLUTION

A system that turns short dashcam clips into labelled training data and pays the driver for it within seconds.

DRIVE

A low-cost dashcam kit that captures footage along with motion and weather data, so each clip shows not just what happened but what led to it.

LABEL

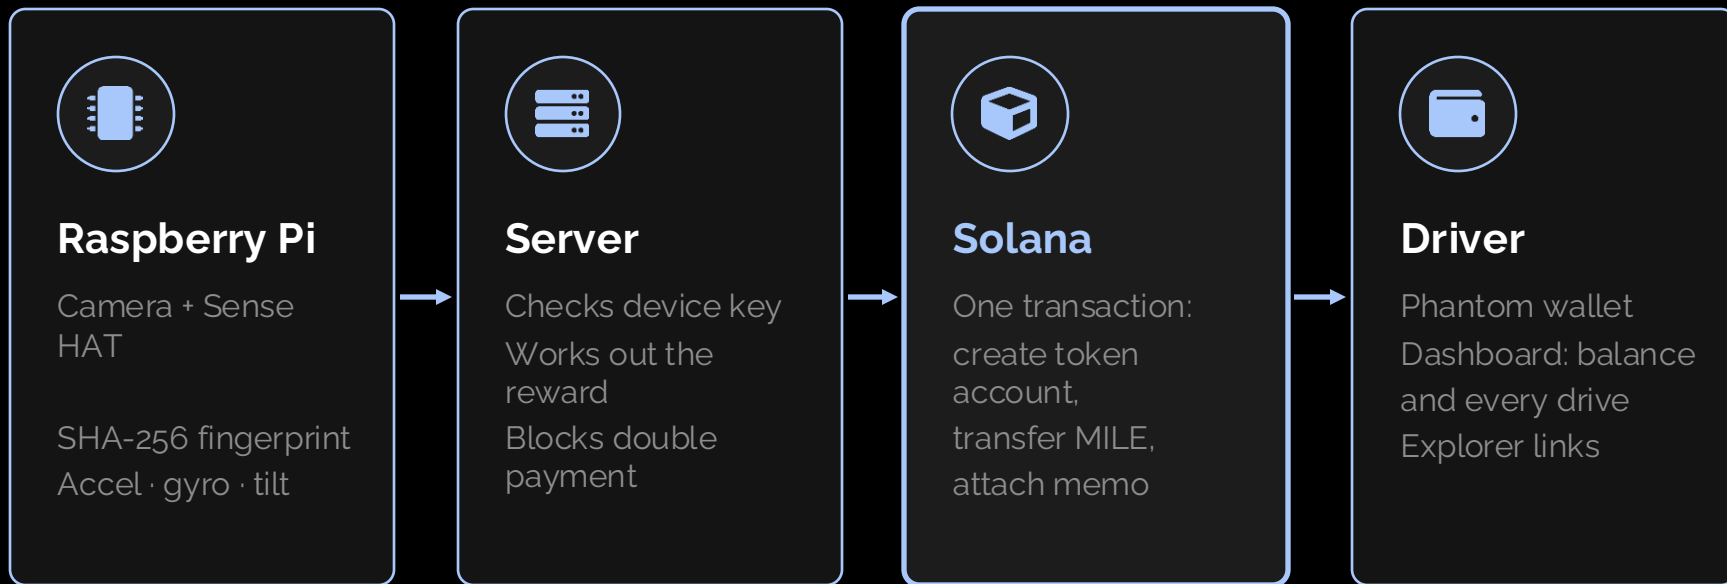

An AI model labels the footage, and the sensor data automatically flags the valuable moments, so rare and risky situations earn more than empty roads.

PAY

Solana then pays the driver within seconds based on the value of the footage, with fees of a fraction of a cent, making it worthwhile to pay just a few cents per clip.

HOW IT WORKS

WHY SOLANA

Micro-payouts per drive

Tiny fees make a 3 MILE payout worthwhile.

Fast confirmation

The driver sees the reward right after the drive.

The chain is the database

History and duplicate checks come from memos.

Transparent and auditable

Anyone can check any payout on Solana Explorer.

Standard token

MILE is SPL Token-2022: any Solana wallet.

A PAYOUT MEMO, ON-CHAIN

FUTURE EXPANSION

Today

A Raspberry Pi, a Sense HAT and a webcam, plugged into a laptop on the passenger seat. This is the rig every clip in the demo came from.

Production

One sealed housing. Camera forward, motion sensors inside, no LED matrix on the dash, USB-C to the car. It ships paired to the driver's wallet.
